# Lecture 24: The Sample Variance $S^2$ The squared variation

Suppose we have *n* numbers  $x_1, x_2, ..., x_n$ . Then their squared variation

$$sv = sv(x_1, x_2, ..., x_n) \ sv(x_1, x_2, ..., x_n) = \sum_{i=1}^{n} (x_i - \overline{x})^2$$

Their <u>mean</u> (average) squared variation msv or  $\sigma_n^2$  (denoted  $\sigma^2$  and called the "population variance on page 33 of our text) is given by

$$msv = \sigma_n^2 = \frac{1}{n}sv = \frac{1}{n}\sum_{i=1}^n (x_i - \overline{x})^2$$

Here  $\overline{x}$  is the average  $\frac{1}{n} \sum_{i=1}^{n} x_i$ .

The msv measure how much the numbes  $x_1, x_2, ..., x_n$  vary (precisely how much they vary from their average  $\overline{x}$ ). For example if they are all equal then they will be all equal to their average  $\overline{x}$  so

$$sv = 0$$
 and  $msv = 0$ 

We also define the sample variance  $s^2$  by

$$S^2 = \frac{1}{n-1}sv = \frac{n}{n-1}msv$$

$$S^{2} = \frac{1}{n-1} \sum_{i=1}^{n} (x_{i} - \overline{x})^{2}$$

Amazingly,  $s^2$  is more important then msv in statistics

## The Shortcut Formula for the Squared Variation

#### **Theorem**

$$sv(x_1, x_2, ..., x_n) = \sum_{i=1}^n x_i^2 - \frac{1}{n} (\sum_{i=1}^n x_i)^2$$
 (\*)

#### **Proof**

Note since 
$$\overline{x} = \frac{1}{n} \sum_{i=1}^{n} x_i$$
 we have  $\sum_{i=1}^{n} x_i = n\overline{x}$ 

Now

$$\sum_{i=1}^{n} (x - i - \overline{x})^2 = \sum_{i=1}^{n} (x_i^2 - 2x_1 \overline{x} + \overline{x})^2$$

$$= \sum_{i=1}^{n} x_1^2 - \sum_{i=1}^{n} 2 \overline{x_i} \overline{x} + \sum_{i=1}^{n} \overline{x^2}$$

$$= \sum_{i=1}^{n} x_1^2 - 2\overline{x} \sum_{i=1}^{n} x_i + \overline{x}^2 \sum_{i=1}^{n} 1$$

## Proof (Cont.)

$$= \sum_{i=1}^{n} x_i^2 - 2\overline{x}(n\overline{x}) + n\overline{x}^2$$

$$= \sum_{i=1}^{n} x_i^2 - 2n\overline{x}^2 + n\overline{x}^2$$

$$= \sum_{i=1}^{n} x_i^2 - n\overline{x}^2$$

$$= \sum_{i=1}^{n} x_i^2 - n\left(\frac{\sum_{i=1}^{n} x_i}{n}\right)^2$$

# Corollary 1

Divide both sides of (\*) by n to get

$$msv = \frac{1}{n} \sum_{i=1}^{n} x_1^2 - \frac{1}{n^2} \left( \sum_{i=1}^{n} x_i \right)^2$$

# Corollary 2 ((Shortcut formula for $s^2$ ))

Divide both sides of (\*) by n-1 to get

$$S^{2} = -\frac{1}{n-1} \sum_{i=1}^{n} x_{i}^{2} - \frac{1}{n(n-1)} \left( \sum_{i=1}^{n} x_{i} \right)^{2}$$

It is this last formula that we will need.

Let met give a conceptual proof of the theorem the way a professorial mathematician would prove the theorem.

#### Definition

A polynomial  $p(x_1, x_2, ..., x_n)$  is symmetric, if it is unchanged by permuting the variables.

#### Examples 3

$$p(x, y, z) = x^2 + y^2 + z^2$$
 is symmetric  $p(x, y, z) = xy + z^2$  is not symmetric

#### **Theorem**

Any symmetric polynomial pin  $x_1, x_2, ..., x_n$  can be rewritten as a polynomial in the power sums  $\sum_{i=1}^{n} x_i^k$  that is

$$p(x_1,\ldots,x_n)=q(\sum x_i,\sum x_1^2,\ldots,\sum x_i^\ell)$$

if deg  $p = \ell$ .

#### **Bottom Line**

 $sv = \sum_{i=1}^{n} (x_i - \overline{x})^2$  is a symmetric polynomial in  $x_1, x_2, \dots, x_n$  so there exist a and b with

$$sv(x_1, x_2, ..., X_n) = a \sum_{i=1}^n x_i^2 + b \left(\sum_{i=1}^n x_i\right)^2$$
 (\*\*)

This is true for all  $x_1, \ldots, x_n$  (an "identify") so we just choose  $x_1, \ldots, x_n$  cleverly to get a and b.

First choose  $x_1 = 1$ ,  $x_2 = -1$ ,  $x_3 = ... = x_n = 0$  so  $\sum_{i=1}^n x_i = 0$  and  $\sum_{i=1}^n x_i^2 = 2$ 

since  $\overline{x} = 0$ 

and 
$$sv(1, -1, 0, \dots, 0) = \sum_{i=1}^{n} (x_i - \overline{x})^2 = \sum_{i=1}^{n} x_i^2$$

(\*\*) becomes

$$2 = a2 + b(0)$$
 so  $a = 1$ 

To find *b* take all the *x*'s to be 1. so  $\overline{x} = 1$  and sv(1, 1 : 1) = 0 (there is no variation in the *x*'s)

$$\sum_{i=1}^{n} x_1^2 = n, \quad \sum_{i=1}^{n} x_i = n \text{ so}$$

$$sv(x_1, \dots, x_n) = \sum_{i=1}^{n} x_i^2 + b(\sum_{i=1}^{n} x_i)^2$$

gives as

$$0 = h + bn^2$$
 so  $b = -\frac{1}{n}$ 

and

$$sv(x_1, x_2, ..., x_n) = \sum_{i=1}^n x_i^2 - \frac{1}{n} (\sum x_i)^2$$

as before.

#### Remark 1

Any symmetric quadratic function  $q(x_1, x_2, ..., x_n)$  is a linear combination of  $\sum_{i=1}^{n} x_i^2$  and  $(\sum_{i=1}^{n} x_i)^2$  that is

$$q(x_1,...,x_n) = a \sum_{i=1}^n x_i^2 + b \left(\sum_{i=1}^n x_i\right)^2$$

## In Which We Return to Statistics

Estimating the Population Variance We have seen that  $\overline{X}$  is a good (the best) estimator of the population mean- $\mu$ , in particular it was an unbiased estimator.

$$E(\overline{X}) = \mu$$
 sample mean papulation mean random variable

How do we estimate the population variance?

$$X$$
 $V(x) = \sigma^2$ 
 $x_1, x_2, \dots, x_n \to s^2 = \frac{1}{n-1} \sum_{i=1}^n (x_i - \overline{x})^2$ 

Answer - use the Sample variance  $s^2$  to estimate the population variance  $\sigma^2$ The reason is that if we take the associated sample variance random variable

$$S^{2} = \frac{1}{n-1} \sum_{i=1}^{n-1} (X_{i} - \overline{X})^{2}$$

then we have

## **Amazing Theorem**

Amazing Theorem

$$E(S^{2}) = \sigma^{2}$$
Sample Population Variance

Why do you need  $\frac{1}{n-1}$ ? We will see.

Before starting the proof we first note the Corollary 2, page 2 implies

## Proposition (Shortcut formula for the sample variance random variable's)

$$S^{2} = \frac{1}{n-1} \sum_{i=1}^{n} X_{i}^{2} - \frac{1}{n(n-1)} \left( \sum_{i=1}^{n} X_{i} \right)^{2}$$
 (b)

Why does this follow from the formula for s<sup>2</sup>? We will also need the following

## Proposition

Suppose Y is a random variable then

$$E(Y^2) = E(Y)^2 + V(Y)$$
 (#)

#### Proof.

$$V(Y) = E(Y^2) - (E(Y))^2$$

(Shortcut formula for V(Y)

# Corollary

Suppose  $X_1, X_2, ..., X_n$  is a random sample from a population of mean  $\mu$  and variance  $\sigma^2$ . Then

- (i)  $E(X_i^2) = \mu^2 + \sigma^2$
- (ii)  $E(T_0) = n^2 \mu^2 + n\sigma^2$

## Proof.

- (i)  $E(X_i) = \mu$  and  $V(Y) = \sigma^2$  so plug into (#)
- (ii)  $E(T_0) = n\mu$  and  $V(T_0) = n\sigma^2$  so plug into (#)

We can now prove (b)

$$E(S^{2}) = E\left(\frac{1}{n-1}\sum_{i=1}^{n}X_{i}^{2} - \frac{1}{n(n-1)}(\sum X_{i})^{2}\right)$$

since E is linear

$$=\frac{1}{n-1}\sum_{i=1}^{n}E(X_{i}^{2})-\frac{1}{n(n-1)}E(T_{0}^{2})$$

by (i) and (ii)

$$= \frac{1}{n-1} \sum_{i=1}^{n} (\mu^{2} + \sigma^{2}) - \frac{1}{n-1} \frac{1}{n} (n^{2}\mu^{2} + n\sigma^{2})$$

$$= \frac{1}{n-1} \left[ n\mu^{2} + n\sigma^{2} - \frac{1}{n} (n^{2}\mu^{2} + n\sigma^{2}) \right]$$

$$= \frac{1}{n-1} \left[ n\mu^{2} + n\sigma^{2} - n\mu^{2} - \sigma^{2} \right]$$

$$= \frac{1}{n-1} \left[ (n-1)\sigma^{2} \right]$$

$$= \sigma^{2}$$

Amazing - you need  $\frac{1}{n-1}$  not  $\frac{1}{n}$ .
